OBESITY MANAGEMENT AS CARDIOVASCULAR RISK IN METABOLIC SYNDROME

RODICA MARIA ONOFREI

University Transilvania Brasov

Keywords: Obesity, Metabolic syndrome, Management

Abstract: Increased prevalence and aggressiveness of cardio-metabolic diseases justifies the growing interest worldwide in tracking and monitoring patients at risk of developing metabolic syndrome. Increased frequency of obesity and overweight with involvement and the succeeding metabolic status of weight gain more than 20% of ideal weight contributes to the diagnosis of metabolic syndrome. Obesity may be a consequence of metabolic disorders or repercussions of improper lifestyle but produces or is triggered by metabolic disorders and cardiovascular risk and represents a risk factor. The management of obesity as a risk factor associated with metabolic syndrome is the prerequisite of good medical diagnosis and treatment conduct.

Cuvinte cheie: obezitate, sindrom metabolic, management

Rezumat: Prevalența crescută și agresivitatea afecțiunilor cardiometabolice justifică interesul crescând pe plan mondial în depistarea și supravegherea pacienților cu risc de a dezvolta sindrom metabolic. Frecvența crescută a supragreutății și obezității cu implicații metabolice ce succed starea de creștere în greutate cu mai mult de 20% din greutatea ideală contribuie la diagnosticarea sindromului metabolic. Obesitatea poate fi consecința tulburărilor metabolicce sau repercusiunea unui stil de viață necorespunzător dar care produce sau este declanșată de tulburări metabolice și reprezintă un factor de risc cardiovascular. Managementul obezității ca factor de risc asociat sindromului metabolic reprezintă premisa unei bune conduit medicale de diagnosticare și tratament al acesteia.

The old methodology for assessing the degree of obesity (Broca's formula, Lorentz) and reporting to ideal weight, is not having the same predictive value as the newly adopted methodology, which is more important for cardiovascular risk assessment is the distribution of body fat.

Anthropometric assessment of obesity is achieved by:
- body mass index (BMI)
- abdominal index (IAF)
- waist measurement

Defining the degree of obesity will be made by using BMI and waist values indicate the distribution of body fat, presence of insulin resistance and cardiovascular risk.

Increased waist suggests increased cardiovascular risk, although BMI remains constant (1).

Risk factors and causative of obesity, genetic and won (alcohol, smoking, sedentary lifestyle, hormonal) production by complex disturbances of behavior, food intake regulation and energy expenditure (3,4).

Contribute to the development of obesity and metabolic lipid disturbance, increased lipogenesis and reduced lipolysis.

Metabolic complications of obesity are complex:
- Carbohydrate metabolism
- Insulin resistance in obesity is due to a combination of

CLINICAL ASPECTS

defects at the receptor and before receptor action of insulin. Not all obese are insulin resistant, but only half of those with a BMI greater than 28kg/m2. Instead 40% of insulin resistance obese become diabetic after 40 years of development.

- Lipid metabolism
  Obesity has a pronounced effect on VLDL metabolism. HyperTG is common and the degree of obesity correlated with TG level (5.6).
- Uric acid metabolism
  There is a strong link between body weight and uric acid levels. in obesity.
- Cardiovascular complication
  Almost invariably accompanies obesity hypertension. The frequency of hypertension among obesity is 50-90%. Cause and effect between the relationship of obesity and hypertension is proven to lower high blood pressure with weight loss (5).
  Atherosclerosis, obesity appears to favor the development of ATS with approximately 10 years earlier due to an accumulation of vascular risk factors (dyslipidemia, sedentary lifestyle, hypertension).
  Heart failure is favored by the extra effort required of the heart, hemodynamic changes induced pulmonary circulation and systemic circulation, fatty infiltration of the pericardium and myocardium.
  Therapeutic targets in obesity management concerns: weight loss, new weight maintenance, prevention of obesity and lifestyle improvement is always having to review and control the complications of obesity associated conditions adapted to the risk class of patients (7).

Therapeutic Program:

- energy-restricted diet, reducing calorie intake is very important in view that each kilogram of fat is 7000 kcal. Featured were two types of diets:
  - deficient diet 500 kcal / day compared to the previous diet. It seeks to effect weight loss of 0.5 to 1 kg per week, 5 to 10 pounds in three months (approximately 5-10% of initial weight). This type of diet recommended in patients with overweight 1MC fall in group (BMI between 25 to 29.9 kg/m2).
  - deficient diet 1000 kcal / day compared with previous feeding. It seeks to effect weight loss of 1-2 pounds per week, approximately 20% of initial weight. This type of diet has been recommended for patients rated as obese BMI group I / II (BMI between 33-37 kg/m2).

Regarding recommended diets were made following remarks:
- Meals should be split up throughout the day 5-6/zi number;
- Reduce consumption of unsaturated fats, sweets and salt concentrates on how possible.
- Exercise - the main modality of power consumption, is recommended both to prevent obesity, as well as its therapeutic method. Important in weight loss relationship is that low intensity to be less physical effort in weight loss, and will double in maintaining the new weight.
- Pharmacological therapy is associated with caloric regime, lipids, under the blood pressure control and heart rate in respect of any contraindications.
  Optimizer also includes lifestyle and the recommendation to avoid alcohol and smoking cessation.

Ensure proper management of cardiovascular risk factors associated with metabolic syndrome requires effective communication and physician - patient aimed at optimizing the patient’s lifestyle, therapeutic monitoring and ensuring psychological support.
